

# EXPERIMENTAL DESIGN

---

---

---

---

---

---

---

## EXPERIMENTAL RESEARCH

Experimental research is an attempt by the researcher to maintain control over all factors that may affect the result of an experiment. In doing this, the researcher attempts to determine or predict what may occur.

---

---

---

---

---

---

---

## OVERVIEW OF EXPERIMENTAL RESEARCH

### Traditional type of research

- Laboratory Experiments
- Field Experiments
- Natural Experiments

Purpose is to investigate cause-and-effect relationships among variables

- Experimental groups vs. control groups
- Each group of participants receives a different treatment
- Always involves manipulation of the independent variable

Answers the question “What will be?”

---

---

---

---

---

---

---

## EXPERIMENTAL DESIGN

**Experimental design is a blueprint of the procedure that enables the researcher to test his hypothesis by reaching valid conclusions about relationships between independent and dependent variables.**

---

---

---

---

---

---

---

## SYSTEMATIC PROCEDURES

More than any other type of research, experimental research should follow a definite, orderly procedure

### Specific steps

---

---

---

---

---

---

---

## STEPS IN EXPERIMENTAL RESEARCH

1. State the research problem
2. Determine if experimental methods apply
3. Specify the independent variable(s)
4. Specify the dependent variable(s)
5. State the tentative hypotheses
6. Determine measures to be used
7. Pause to consider potential success
8. Identify intervening (extraneous) variables
9. Formal statement of research hypotheses
10. Design the experiment
11. Final estimate of potential success
12. Conduct the study as planned
13. Analyze the collected data
14. Prepare a research report

---

---

---

---

---

---

---

## RESEARCH ESSENTIALS

- Manipulation of an independent variable
- All variables except the dependent variable are held constant (control)
- Manipulation of the dependent variable by the independent variable is observed (observation)

---

---

---

---

---

---

## EXPERIMENTAL CONTROL

Experimental control attempts to predict events that will occur in the experimental setting by neutralizing the effects of other factors

---

---

---

---

---

---

## CONTROL METHODS

- Physical control
- Selective control
- Statistical control

---

---

---

---

---

---

## PHYSICAL CONTROL

- Gives all subjects equal exposure to the independent variable
- Controls non-experimental variables that effect the dependent variable

---

---

---

---

---

---

## SELECTIVE CONTROL

Indirectly manipulate by selecting in or out variables that cannot be controlled

---

---

---

---

---

---

## STATISTICAL CONTROL

Variables not conducive to physical or selective manipulation may be controlled by statistical techniques

---

---

---

---

---

---

## INTERNAL VALIDITY

Did the experimental treatment make the difference in this specific instance rather than extraneous variables?

---

---

---

---

---

---

---

## INTERNAL VALIDITY FACTORS

1. History
2. Maturation
3. Pre-testing
4. Measuring instruments
5. Statistical regression
6. Differential selection
7. Experimental mortality
8. Interaction of factors

---

---

---

---

---

---

---

## HISTORY

The events occurring between the first and second measurements in addition to the experimental variable which might affect the measurement

---

---

---

---

---

---

---

## MATURATION

The process of maturing which takes place in the individual during the duration of the experiment which is not a result of specific events but of simply growing older, growing tired or similar changes

---

---

---

---

---

---

## PRE-TESTING

The effect created on the second measurement by having a measurement before the experiment

---

---

---

---

---

---

## MEASURING INSTRUMENTS

Changes in instruments, calibration of instruments, observers or scorers may cause changes in the measurements

---

---

---

---

---

---

## STATISTICAL REGRESSION

Where groups are chosen because of extreme scores of measurements, those scores tend to move toward the mean with repeated measurements even without an experimental variable

---

---

---

---

---

---

## DIFFERENTIAL SELECTION

Different individuals or groups have different previous knowledge or ability which would affect the final measurement if not taken into account

---

---

---

---

---

---

## EXPERIMENTAL MORTALITY

The loss of subjects from comparison groups could greatly affect the comparisons because of unique characteristics of those subjects. Groups to be compared need to be the same as before the experiment

---

---

---

---

---

---

## INTERACTION OF FACTORS

Combinations of many of these factors may interact especially in multiple group comparisons to produce erroneous measurements

---

---

---

---

---

---

---

## EXTERNAL VALIDITY

To what populations, settings, treatment variables and measurement variables can this observed effect be generalized?

---

---

---

---

---

---

---

## EXTERNAL VALIDITY FACTORS

1. Pre-testing
2. Differential selection
3. Experimental procedures
4. Multiple treatment interference

---

---

---

---

---

---

---

## PRE-TESTING

Individuals who were pre-tested might be less or more sensitive to the experimental variable or might have learned from the pre-test making them unrepresentative of the population who had not been pre-tested

---

---

---

---

---

---

## DIFFERENTIAL SELECTION

The selection of the subjects determines how the findings may be generalized. Subjects selected from a small group or one with particular characteristics would limit generalizability

---

---

---

---

---

---

## EXPERIMENTAL PROCEDURES

The experimental procedures and arrangements have a certain amount of effect on the subjects in the experimental settings

---

---

---

---

---

---

## MULTIPLE TREATMENT INTERFERENCE

If the subjects are exposed to more than one treatment, then the findings could only be generalized to individuals exposed to the same treatments in the same order of presentation

---

---

---

---

---

---

---

## TOOLS TO CONTROL VALIDITY JEOPARDIZING FACTORS

- Pre-test
- Control group
- Randomization
- Additional groups

---

---

---

---

---

---

---

## TYPES OF DESIGNS

The basic structure of a research study . . . particularly relevant to experimental research

Types of designs (Campbell & Stanley, 1963)

- Pre-experimental
- True experimental
- Quasi-experimental

---

---

---

---

---

---

---

## PRE-EXPERIMENTAL DESIGNS

- Weak experimental designs in terms of control
- No random sampling
- Threats to internal and external validity are significant problems
- Many definite weaknesses

Example: One-group pretest/posttest

---

---

---

---

---

---

---

## TRUE EXPERIMENTAL DESIGNS

- Best type of research design because of their ability to control threats to internal validity
- Utilizes random selection of participants and random assignment to groups

Example: Pretest/posttest control group design

---

---

---

---

---

---

---

## QUASI-EXPERIMENTAL DESIGNS

- These designs lack either random selection of participants or random assignment to groups
- They lack some of the control of true experimental designs, but are generally considered to be fine

Example: Nonequivalent group design

---

---

---

---

---

---

---

## EXPERIMENTAL DESIGNS

Pre-Experimental

Quasi-Experimental

True-Experimental

Question:

*"Does protein supplementation increase muscle hypertrophy?"*

---

---

---

---

---

---

---

## PRE-EXPERIMENTAL DESIGNS

One Shot Study

---

---

---

---

---

---

---

## PRE-EXPERIMENTAL DESIGNS

One Group Pre-test Post-test

---

---

---

---

---

---

---

## PRE-EXPERIMENTAL DESIGNS

### Static Group Comparison

---

---

---

---

---

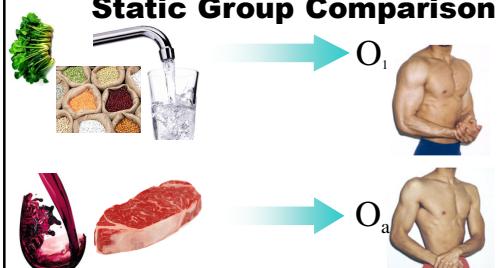

---

---

## PRE-EXPERIMENTAL DESIGNS

### Static Group Comparison

---

---

---

---

---

---

---

## QUASI-EXPERIMENTAL DESIGNS

### Pre-test Post-test Group Comparison

---

---

---

---

5. Solomon Four-Group Design	+	+	+	+	+	+	+	—	?
	D	—	X	—	—	—	—	—	—
6. Posttest-Only Control-Group Design	+	+	+	+	+	+	+	—	?
	D	—	—	—	—	—	—	—	—

Notes: In the tables, a minus indicates a definite weakness; a plus indicates that the factor is one possible source of concern; and a blank indicates that the factor is not relevant.  
 1. It is the general reluctance that other summary tables are presented because they are not to be "too helpful," and to be depended upon in place of the more complex and qualified presentation in the article. This is a reasonable attitude, but it is also important that the reader understand these. In particular, it is against the spirit of this presentation to create uninterpretable kinds of or misleading descriptive designs.

TABLE II SOURCES OF INVALIDITY FOR QUASI-EXPERIMENTAL DESIGNS 7 THROUGH 12									
	Sources of Invalidity								
	General External								
	Histories	Motivation	Testing	Instrumentation	Regression	Schedule	Maturing	Interventions of X	X
